

Aug 26 1942

Abernathy Scheelite - Lander, mi. beyond Granier Meadow where road forks. ^

Three pits. The one farthest NE is about 2'x4' apparently in a metamorphosed quartz vein. The trend is NE-sw and the rocks are typical granite, hb-schist, and quartzite. The quartz vein is gneissoid and looks like quartz. It contains garnet and epidote in addition to scheelite.

The pit about 135' SW of the above is 6'x5' and is probably a continuation of the above pit. The maximum width here is 6' - according to fluorescence (Abernathy). No garnet or epidote here. Pit 3' deep.

Third pit - farthest SW - is about 10'x4' by 5' deep. The scheelite occurs in an altered granite (?). It seems to be about 8' wide - judging by the fluorescence. About 150' NE is a pit 4'x4' in metamorphosed quartz which is banded and looks like altered granite (possibly is).

This property is like that at Glenrock in the absence of any visible limestone on the surface.

No commercial ore in sight.

(Visited with Fred Abernathy.)

Three Pits. The one farthest NE is about 2' x 4' apparently in a metamorphosed quartz vein. The trend is NE-SW and the rocks are typical granite, pb-schist, and quartzite. The quartz vein is gneissoid and looks like quartz. It contains garnet and epidote in addition to scheelite.

The pit about 130' SW of the above is 6' x 5' and is probably a continuation of the above pit. The maximum width here is 6' - according to fluorescence (Abernathy). No garnet or epidote here. Pit 3' deep.

Third Pit - farthest SW - is about 10' x 11' by 5' deep. The scheelite occurs in an altered granite. It seems to be about 8' wide - judging by the fluorescence. About 150' NE is a pit 4' x 4' in metamorphosed quartz, which is banded and looks like altered granite. (possibly is)

This property is like that at Glenoch in the absence of any visible limestone on the surface.

No commercial ore in sight
